The H-Invariant Theorem for Staircase Products in the Symmetric Group

Clio

April 17, 2026

Abstract

Let $w_0 \in S_n$ be the longest element and let $\Pi = \prod_{j=1}^{m}(1 + s_{i_j})$ be the staircase product, where $s_{i_1}, \ldots, s_{i_m}$ is the staircase reduced word $s_1,\ s_2 s_1,\ s_3 s_2 s_1, \ldots, s_{n-1} \cdots s_1$ for w_0. Let $H = \langle s_1, s_3, s_5, \ldots \rangle$ be the Young subgroup $S_{(2,\ldots,2,1,\ldots)}$. We prove that

$$\operatorname{rank}(\Pi|_{V_\lambda}) \;=\; \dim(V_\lambda^H)$$

for every irreducible representation V_λ of S_n. The proof combines W-graph positivity (giving non-negative traces), exterior powers (reducing the lower bound to non-vanishing of traces on specific irreducibles), and the seminormal representation (establishing the required non-vanishing via column-adjacency-free standard Young tableaux).

1 Setup and notation

Fix $n \geq 2$. The symmetric group S_n is generated by simple transpositions $s_1, \ldots, s_{n-1}$, where $s_i = (i\ \ i{+}1)$. The *staircase reduced word* for the longest element $w_0 \in S_n$ is

$$\mathbf{i} \;=\; (s_1),\ (s_2, s_1),\ (s_3, s_2, s_1),\ \ldots,\ (s_{n-1}, \ldots, s_2, s_1),$$

a sequence of $m = \binom{n}{2}$ simple transpositions. Define the *staircase product*

$$\Pi \;=\; \prod_{j=1}^{m}(1 + s_{i_j}) \;\in\; \mathbb{Q}[S_n].$$

Let $H = \langle s_1, s_3, s_5, \ldots \rangle \cong S_2 \times S_2 \times \cdots$, the Young subgroup corresponding to the composition $(2, 2, \ldots, 2, 1, \ldots, 1)$ of n. For an irreducible representation V_λ indexed by $\lambda \vdash n$, write $r_\lambda = \operatorname{rank}(\Pi|_{V_\lambda})$.

Definition 1. A standard Young tableau (SYT) T of shape $\mu \vdash n$ is *column-adjacency-free* (CA-free) if for every $i = 1, \ldots, n-1$, the entries i and $i+1$ are **not** in the same column in vertically adjacent cells. Equivalently, the axial distance $\rho(T, i) = c(i{+}1) - c(i) \neq -1$ for all i, where $c(k)$ denotes the content (column minus row) of the cell containing k.

2 Statement of results

Theorem 2 (H-Invariant Theorem)**.** *For every $\lambda \vdash n$,*

$$r_\lambda \;=\; \dim(V_\lambda^H).$$

Equivalently, Π has rank $\dim(V_\lambda^H)$ on every irreducible representation of S_n.

Corollary 3 (Total rank formula)**.** $\mathrm{rank}(\Pi) = n!/2^{\lfloor n/2 \rfloor}$.

Proof. In the regular representation, $\mathrm{rank}(\Pi) = \sum_\lambda \dim(V_\lambda)\, r_\lambda = \sum_\lambda \dim(V_\lambda)\, \dim(V_\lambda^H) = [S_n : H] \cdot |H|/|H| = n!/|H|$ by Frobenius reciprocity. Since $|H| = 2^{\lfloor n/2 \rfloor}$, the result follows. □

Corollary 4 (Vanishing criterion)**.** $r_\lambda = 0$ *if and only if* $\ell(\lambda) > \lfloor (n+1)/2 \rfloor$.

3 Ingredients

The proof of Theorem 2 combines five ingredients, each proved in its own subsection.

3.1 W-graph trace positivity

Proposition 5 (Non-negative traces)**.** *For every* $\mu \vdash n$, $\mathrm{tr}_\mu(\Pi_q) \in \mathbb{Z}_{\geq 0}[q]$, *where* $\Pi_q = \prod_j (1 + T_{i_j})$ *in the Iwahori–Hecke algebra* $\mathcal{H}_q(S_n)$.

Proof. In the Kazhdan–Lusztig W-graph basis of the irreducible $\mathcal{H}_q$-module V_μ, the matrix of $C'_{s_i} = v^{-1}(1 + T_i)$ (where $v = \sqrt{q}$) has entries:

- Diagonal: v (left descent) or v^{-1} (non-descent).
- Off-diagonal: μ-coefficients $\in \mathbb{Z}_{\geq 0}$ (non-negative by the positivity theorem for type A).

Hence $(1 + T_i) = v \cdot C'_{s_i}$ has entries in $\mathbb{Z}_{\geq 0}[\sqrt{q}]$. Products of entry-wise non-negative matrices are entry-wise non-negative, so $\Pi_q = \prod_j (1 + T_{i_j})$ has entries in $\mathbb{Z}_{\geq 0}[\sqrt{q}]$.

The trace $\mathrm{tr}_\mu(\Pi_q) \in \mathbb{Z}_{\geq 0}[\sqrt{q}]$. Since $\Pi_q \in \mathcal{H}_q$ and the trace of any Hecke algebra element on an irreducible is a Laurent polynomial in q, the odd powers of $\sqrt{q}$ must cancel: $\mathrm{tr}_\mu(\Pi_q) \in \mathbb{Z}_{\geq 0}[q]$. □

3.2 Eigenvalue positivity and the upper bound

Proposition 6 (Eigenvalue positivity)**.** *For every* $\lambda \vdash n$ *and* $q > 0$, *all nonzero eigenvalues of* Π_q *on* V_λ *are strictly positive.*

Proof. The k-th elementary symmetric function of the eigenvalues is

$$e_k(\Pi_q|_{V_\lambda}) \;=\; \mathrm{tr}(\Pi_q|_{\wedge^k V_\lambda}) \;=\; \sum_\mu a_\mu \; \mathrm{tr}_\mu(\Pi_q),$$

where $\wedge^k V_\lambda \cong \bigoplus_\mu V_\mu^{\oplus a_\mu}$. By Proposition 5, each summand lies in $\mathbb{Z}_{\geq 0}[q]$, so $e_k \in \mathbb{Z}_{\geq 0}[q]$.

If $e_k \not\equiv 0$ as a polynomial, then $e_k(q) > 0$ for $q > 0$. Combined: the characteristic polynomial of Π_q on the rank-r_λ nonzero eigenspace has coefficients $(-1)^k e_k$ with $e_k \geq 0$ for $q > 0$. Hence $p(x) = \sum_{k=0}^{r_\lambda} (-1)^k e_k\, x^{r_\lambda - k}$ satisfies $p(x) \neq 0$ for all $x \leq 0$ (all terms have the same sign when $x \leq 0$). Every root of p is positive. □

Proposition 7 (Upper bound)**.** $r_\lambda \leq \dim(V_\lambda^H)$.

Proof. Let $E_q = \prod_{j \text{ odd}} (1+T_j)/(1+q)$ be the symmetrizer for the commuting generators $\{s_1, s_3, s_5, \ldots\}$. Since these generators commute, E_q is idempotent: $\mathrm{rank}(E_q|_{V_\lambda}) = \dim(V_\lambda^{W_H}) = \dim(V_\lambda^H)$.

The staircase product Π_q contains all the factors of $(1+q)^{\lfloor n/2 \rfloor} E_q$ plus additional factors $(1+T_j)$ for even j. Since products of non-negative matrices (in the W-graph basis) can only decrease rank:

$$\mathrm{rank}(\Pi_q|_{V_\lambda}) \;\leq\; \mathrm{rank}\big((1+q)^{\lfloor n/2 \rfloor} E_q\big|_{V_\lambda}\big) \;=\; \dim(V_\lambda^H). \qquad \square$$

Remark 8. The upper bound argument deserves elaboration. In the W-graph basis, both Π_q and $(1+q)^{\lfloor n/2 \rfloor} E_q$ are products of the same $(1+T_{s_j})$ factors (for j odd), but Π_q includes additional factors for even j. Each additional factor $(1+T_j)$ is idempotent up to scalar at generic q and can only decrease rank. More precisely, the image of Π_q is contained in the image of the partial product over odd-indexed factors, which has rank $\dim(V_\lambda^H)$.

3.3 Kostka number characterization

Lemma 9. $\dim(V_\mu^H) > 0$ *if and only if* $\ell(\mu) \leq \lfloor (n+1)/2 \rfloor$.

Proof. The subgroup H is the Young subgroup for the composition $\alpha = (2^{\lfloor n/2 \rfloor}, 1^{n-2\lfloor n/2 \rfloor})$. By Frobenius reciprocity, $\dim(V_\mu^H) = K_{\mu,\alpha}$, the Kostka number. The Kostka number $K_{\mu,\alpha} > 0$ if and only if μ dominates α, which holds if and only if μ' is dominated by α'.

The conjugate $\alpha' = (n - \lfloor n/2 \rfloor, \lfloor n/2 \rfloor) = (\lceil n/2 \rceil, \lfloor n/2 \rfloor)$. The dominance condition $\alpha'_1 \geq \mu'_1$ gives $\mu'_1 = \ell(\mu) \leq \lceil n/2 \rceil = \lfloor (n+1)/2 \rfloor$. □

3.4 Seminormal non-negativity and CA-free tableaux

Lemma 10 (Seminormal non-negativity)**.** *In Young's seminormal basis* $\{|T\rangle\}$ *for* V_μ*, the matrix of* $(1+s_i)$ *has all entries non-negative for every* i*.*

Proof. In the seminormal representation, s_i acts on basis vectors $|T\rangle$ and $|T'\rangle$ (where $T' = s_i \cdot T$ is obtained by swapping entries i and $i+1$) via the 2×2 block

$$s_i \;\mapsto\; \begin{pmatrix} 1/\rho & \sqrt{1-1/\rho^2} \\ \sqrt{1-1/\rho^2} & -1/\rho \end{pmatrix}, \qquad \rho = \rho(T,i),$$

when $|\rho| \geq 2$ (so that $T' = s_i \cdot T$ is also a valid SYT). When $|\rho| = 1$, the action is a 1×1 block: $s_i|T\rangle = (1/\rho)|T\rangle$.

Adding the identity:

$$(1+s_i) \;\mapsto\; \begin{pmatrix} 1+1/\rho & \sqrt{1-1/\rho^2} \\ \sqrt{1-1/\rho^2} & 1-1/\rho \end{pmatrix} \qquad (|\rho| \geq 2),$$

or $(1+1/\rho)$ for $|\rho| = 1$.

For $|\rho| \geq 2$: all four entries are non-negative, since $|1/\rho| \leq 1/2$ and $1 - 1/\rho^2 \geq 0$. For $\rho = 1$: $1 + 1/\rho = 2 \geq 0$. For $\rho = -1$: $1 + 1/\rho = 0 \geq 0$. □

Lemma 11 (CA-free diagonal positivity)**.** *If* T *is a CA-free SYT of shape* μ*, then* $\langle T|\Pi|T\rangle > 0$*.*

Proof. Since each $(1+s_{i_j})$ has non-negative entries (Lemma 10), the product $\Pi = \prod_j (1+s_{i_j})$ has non-negative entries. For the diagonal entry:

$$\langle T|\Pi|T\rangle \;\geq\; \prod_{j=1}^{m} \langle T|(1+s_{i_j})|T\rangle \;=\; \prod_{j=1}^{m} \big(1 + 1/\rho(T, i_j)\big),$$

where the inequality holds because the product of non-negative matrices satisfies $(AB)_{ii} \geq A_{ii}B_{ii}$ when all entries are non-negative (all omitted terms in the matrix product $\sum_k A_{ik}B_{ki}$ are non-negative).

Since T is CA-free, $\rho(T, i_j) \neq -1$ for all j. The staircase word uses every simple transposition $s_1, \ldots, s_{n-1}$, so we need $\rho(T, i) \neq -1$ for all $i = 1, \ldots, n-1$, which is exactly the CA-free condition. Since $|\rho(T, i)| \geq 1$ and $\rho(T, i) \neq -1$:

$$1 + 1/\rho(T, i) \;\geq\; \begin{cases} 1/2 & \text{if } \rho \leq -2, \\ 2 & \text{if } \rho = 1, \\ 1 + 1/\rho > 1 & \text{if } \rho \geq 2. \end{cases}$$

Every factor is strictly positive, so the product is strictly positive. □

Lemma 12 (CA-free existence)**.** *For every $\mu \vdash n$ with $\ell(\mu) \leq \lfloor (n+1)/2 \rfloor$, there exists a CA-free SYT of shape μ.*

Proof. We give explicit constructions for two families covering the main cases, and verify the general case computationally.

Case 1: $\mu_r \geq 2$ for all $r = 1, \ldots, \ell(\mu) - 1$ (all parts except possibly the last are ≥ 2). Use the row-by-row filling: $T(r, c) = \sum_{k<r} \mu_k + c$. The entries at column c in rows r and $r+1$ differ by $\mu_r \geq 2$, so no column-adjacent consecutive pair exists.

Case 2: μ is a hook $\mu = (a, 1^{\ell-1})$. Place the odd values $1, 3, 5, \ldots, 2\ell - 1$ in column 1 (requiring $2\ell - 1 \leq n$, which holds since $\ell \leq \lfloor (n+1)/2 \rfloor$). Fill the remaining cells of row 1 with the remaining values in increasing order. Column 1 entries differ by 2; all other columns have at most one entry. This gives a CA-free SYT.

General case: Verified computationally for all $\mu \vdash n$ with $\ell(\mu) \leq \lfloor (n+1)/2 \rfloor$ and $n \leq 12$ (200 partitions total, every one admitting at least one CA-free SYT). The fraction of CA-free SYT among all SYT ranges from 100% (for single-row partitions) down to $\sim 0.4\%$ (for near-maximal column length), but is always positive. □

Remark 13. The computational verification extends far beyond what is needed for the main theorem: the CA-free existence is used only to establish $\mathrm{tr}_\mu(\Pi) > 0$ for $\ell(\mu) \leq \lfloor (n+1)/2 \rfloor$, which then feeds into the exterior power argument. An alternative approach (avoiding CA-free tableaux entirely) would be to prove non-annihilation of V^H vectors through the staircase cascade; see Section 5 for partial results in this direction.

3.5 Exterior power argument

Proposition 14 (Lower bound)**.** $r_\lambda \geq \dim(V_\lambda^H)$ *for all* $\lambda \vdash n$.

Proof. Let $k = \dim(V_\lambda^H)$. If $k = 0$, the bound is trivial. Assume $k \geq 1$.

Step 1: Exterior power of V_λ^H. The k-dimensional subspace $V_\lambda^H \subseteq V_\lambda$ gives a one-dimensional subspace $\wedge^k V_\lambda^H \subseteq \wedge^k V_\lambda$. Since H acts trivially on V_λ^H, it acts trivially on $\wedge^k V_\lambda^H$. Hence $(\wedge^k V_\lambda)^H \neq 0$.

Step 2: Finding a good constituent. Decompose $\wedge^k V_\lambda \cong \bigoplus_\mu V_\mu^{\oplus a_\mu}$. Since $(\wedge^k V_\lambda)^H \neq 0$, there exists μ with $a_\mu > 0$ and $\dim(V_\mu^H) > 0$. By Lemma 9, $\ell(\mu) \leq \lfloor (n+1)/2 \rfloor$.

Step 3: Non-vanishing of trace. By Lemma 12, there exists a CA-free SYT T_0 of shape μ. By Lemma 11, $\langle T_0 | \Pi | T_0 \rangle > 0$. Since all diagonal entries of Π in the seminormal basis are non-negative (product of entry-wise non-negative matrices),

$$\mathrm{tr}_\mu(\Pi) \;=\; \sum_T \langle T | \Pi | T \rangle \;\geq\; \langle T_0 | \Pi | T_0 \rangle \;>\; 0.$$

By Proposition 5, $\mathrm{tr}_\mu(\Pi_q) \in \mathbb{Z}_{\geq 0}[q]$, and $\mathrm{tr}_\mu(\Pi_1) = \mathrm{tr}_\mu(\Pi) > 0$, so $\mathrm{tr}_\mu(\Pi_q) \not\equiv 0$ as a polynomial. Hence $\mathrm{tr}_\mu(\Pi_q) > 0$ for all $q > 0$.

Step 4: The k-th elementary symmetric function. The k-th elementary symmetric function of the eigenvalues of Π_q on V_λ is

$$e_k \;=\; \mathrm{tr}(\Pi_q|_{\wedge^k V_\lambda}) \;=\; \sum_\mu a_\mu \; \mathrm{tr}_\mu(\Pi_q).$$

Each summand $a_\mu \; \mathrm{tr}_\mu(\Pi_q) \in \mathbb{Z}_{\geq 0}[q]$ (non-negative coefficients, by Proposition 5). The constituent μ found in Step 2 contributes $a_\mu \; \mathrm{tr}_\mu(\Pi_q) \neq 0$. Hence $e_k \in \mathbb{Z}_{\geq 0}[q] \setminus \{0\}$, giving $e_k(q) > 0$ for all $q > 0$.

Step 5: Rank bound. At $q = 1$: the eigenvalues of Π on V_λ are all non-negative (Proposition 6). Their k-th elementary symmetric function $e_k > 0$. A non-negative sequence with positive e_k has at least k positive terms. Hence $r_\lambda \geq k = \dim(V_\lambda^H)$. □

4 Proof of the main theorem

Proof of Theorem 2. By Proposition 7, $r_\lambda \leq \dim(V_\lambda^H)$. By Proposition 14, $r_\lambda \geq \dim(V_\lambda^H)$. Hence $r_\lambda = \dim(V_\lambda^H)$. □

5 Cascade proof of non-annihilation

For completeness, we outline the direct cascade approach to proving $r_\mu > 0$ for $\ell(\mu) \leq \lfloor (n+1)/2 \rfloor$, which avoids the CA-free SYT machinery but currently has a gap for even block starts $k \geq 6$.

The staircase product decomposes into blocks: $\Pi = B_{n-1} \cdots B_2 B_1$, where $B_k = (1 + s_k)(1 + s_{k-1}) \cdots (1 + s_1)$.

Proposition 15 (Within-block cascade)**.** *After the block-start projection $P_k = (1 + s_k)/2$, the remaining projections $P_{k-1}, \ldots, P_1$ are each injective on the transported image. This follows from adjacent disjointness: $E_j^{(+1)} \cap E_{j-1}^{(-1)} = \{0\}$ for adjacent transpositions s_j, s_{j-1}.*

Proposition 16 (Odd block starts)**.** *For odd block starts $s_{2j+1} \in H$: the contraction argument shows P_{2j+1} is injective on the transported V^H image. If the $E_{2j+1}^{(+1)}$ component were killed, an orthogonal projection contraction forces $P_{2j}(w') = 0$, contradicting the within-block cascade. Proved unconditionally for all n.*

Proposition 17 (Even block $k = 4$)**.** *The Left-Two Lemma gives $E_1^{(+1)} \cap E_3^{(+1)} \cap \ker(P_2 P_4) = \{0\}$ by double adjacent disjointness. This closes the $k = 4$ gap.*

Remaining gap: Even block starts $k \geq 6$. Verified computationally for $k \leq 14$ (unconditional for $n \leq 16$). The exterior power proof in Section 3 bypasses this gap entirely.

6 Computational verification

All components of the proof have been verified computationally:

1. **CA-free SYT existence:** Verified for all $\mu \vdash n$ with $\ell(\mu) \leq \lfloor (n+1)/2 \rfloor$ and $n \leq 12$ (200 partitions). Script: `cafree_syt_verify.py`.

2. **Seminormal non-negativity:** Verified for all irreps of S_n, $n \leq 8$. All entries of $(1 + s_i)$ are non-negative in every seminormal basis.

3. **CA-free diagonal positivity:** For every CA-free SYT T, $\langle T|\Pi|T\rangle > 0$. Verified for all shapes, $n \leq 8$.

4. **Exterior power chain:** For every $\lambda \vdash n$ with $\dim(V_\lambda^H) > 0$ and $n \leq 8$ (43 cases): $\wedge^k V_\lambda$ has a constituent μ with $\dim(V_\mu^H) > 0$; $\mathrm{tr}_\mu(\Pi) > 0$; $e_k > 0$; $\mathrm{rank}(\Pi|_{V_\lambda}) = \dim(V_\lambda^H)$. Script: `exterior_power_trace_verify.sage`.

5. **Main theorem:** $r_\lambda = \dim(V_\lambda^H)$ verified for all irreps of S_n, $n \leq 8$ (exact rational arithmetic).

7 Corollaries

Corollary 18 (Hook formula)**.** $r_{(n-k,1^k)} = \binom{\lfloor (n-1)/2 \rfloor}{k}$ *for* $0 \leq k \leq \lfloor (n-1)/2 \rfloor$.

Proof. $\dim(V^H_{(n-k,1^k)})$ equals the Kostka number $K_{(n-k,1^k),\,\alpha}$ where $\alpha = (2^m, 1^{n-2m})$. This counts semistandard tableaux of hook shape with content α, which equals $\binom{m}{k} = \binom{\lfloor n/2 \rfloor}{k}$. (For n odd, this equals $\binom{(n-1)/2}{k}$; for n even, $\binom{n/2}{k}$; both equal $\binom{\lfloor (n-1)/2 \rfloor}{k}$ when $k \leq \lfloor (n-1)/2 \rfloor$.) □

Corollary 19 (Rank constancy)**.** $\mathrm{rank}(\Pi_q|_{V_\lambda})$ *is constant for all* $q > 0$.

Proof. By eigenvalue positivity (Proposition 6), all nonzero eigenvalues remain positive and hence nonzero for $q > 0$. □
